

# Biological Imaging using a CMOS or CCD Image Sensor

**IP Status:** Pending US Patent; **Application #:** 09/852,375

## DNA Fluorescence Detection

A method has been developed to acquire digital images and maps of biological samples using an electronic light detector array, for example a CCD or CMOS image sensor. The biological sample may include biological holding structures such as a DNA spot array on a DNA chip and protein bands in a 2D gel. The array allows imaging methods such as fluorescence detection from a biological sample to be analyzed.

### MN-IP Try and Buy

#### Try

- Trial period up to 18 months. \$5000/6 months.
- Fee waived if MN operating company or if sponsoring \$50,000+ in research.

#### Buy

- Exclusive license for a \$20,000 conversion payment.
- No U.S. patent expenses.
- 1.5% Royalty (1.0% for MN companies) after \$1 million in product sales.

## Low Cost Biological Sample Analysis

Current methods of biological sample imaging involve placing a DNA chip on a microscope and moving the stage into focus. Such equipment is expensive and generally requires a high degree of skill and training to operate and maintenance to keep operational. The described technology allows for a less expensive, lower maintenance alternative spot detection method and apparatus for biological sample analysis.

### BENEFITS OF BIOLOGICAL IMAGING USING AN ELECTRONIC LIGHT DETECTOR:

- Simpler biological imaging using an electronic light detector.
- Less expensive and less maintenance than current technology.
- Typical analysis includes DNA Chips, DNA spots and fluorescence analysis

**Phase of Development** **Proof** of concept. Demonstrated in laboratory.

**Researchers:** Martin Blumenfeld, PhD Emeritus faculty, Genetics, Cell Biology and Development Department, College of Biological Sciences
